New diagnostics of our computed correlations — no extracted paper curves
Square: look for a stable exponent
Our singlets, χ=32
Our singlets, χ=64
Our singlets, χ=128
Exact orthogonal dimers
Gray band: paper's 1.16 ± 0.04
Different displacement from our curves
Upward drift: finite-χ cutoff
Effective exponent p
Separation (nearest-neighbor spacings)
Kagome: look for a stable inverse length
χ=18, cutoff 10⁻⁸
χ=32, cutoff 10⁻⁸
χ=32, cutoff 10⁻¹² (unconverged)
A plateau supports exponential decay.
Cutoff dependence still limits precision.
1 cell = 2 nearest-neighbor spacings.
Effective inverse length κ = 1/ξ (cells⁻¹)
Separation (Bravais unit cells)
